2021 Statistics of embryo production and transfer in domestic farm animals

A new milestone has been reached: Transfers of IVP embryos were over one million worldwide

By Joao HM Viana, Chair – IETS Data Retrieval Committee (henrique.viana@embrapa.br)

In: Embryo Technology Newsletter, v. 40, n.4, 2022

1. Executive summary

The International Embryo Technology Society (IETS) Data Retrieval Committee presents the 31st annual report of data collected globally in 2022 on embryo transfer (ET) activities during the year 2021. As highlighted in the last report, in spite of the social and economic consequences of the COVID-19 pandemic, which was still a major global health issue in 2021, the general trends of the embryo industry were very positive around the world.

Minor changes have been observed in the number of countries reporting ET data in 2021, which remained approximately 20% (40 of 195, 20.5%; Table 1). This stability reflects the consistency in data retrieval from countries within the Americas and Europe, but also the lack of more comprehensive information gathered from African and Asian countries. Nevertheless, we were able to use embryo export data to infer about the activity in other 16 countries that imported embryos but did not submit any data to this committee. These data suggest that embryo technologies are currently in use in 28.7% of the countries worldwide.

The data of the embryo industry in 2021 on the four most representative farm animal species are summarized in Table 2 (total of embryos, produced or collected) and Table 3 (numbers of transferred embryos). Altogether, the numbers depict a very positive moment for the industry, with more than 2 million embryos collected or produced in these species alone. The most remarkable increase occurred in cattle. Over 1.5 million in vitro-produced (IVP) embryos were recorded, an increase of 31.5% compared with 2020 (1,521,018 vs. 1,156,422, respectively). Interestingly and divergent from the tendency observed since 2015, the number of in vivo-derived (IVD) embryos collected and transferred in 2021 has also increased compared with 2020 (+6.8% and +6.5%, respectively); yet in lesser proportions than those observed for IVP embryos. The simultaneous grow in the numbers of IVP and IVD embryos recorded led to an overall increase of 25.6% in the world total cattle embryos, the greatest since 2003. This was a general trend, with all top 10 countries in bovine embryo production in 2020 reporting increased numbers in 2021. Worldwide, IVP embryos accounted for, in 2021, 79.7% of all transferrable cattle embryos.

We observed a similar trend in sheep, with both numbers of IVD and IVP embryos increasing in 2021 compared with 2020 (+38.1% and +344.0%, respectively). On the other hand, the increase in the number of horse embryos recorded in 2021 (+9.6%) was mainly driven by an increase in IVP activity (+34.5%), whereas the number of IVD embryos remained similar to 2020 (25,475 vs. 25,219, respectively; +1.0%). In goats, the increase in the number of IVP embryos (+179.3%) was partially compensated by a decrease in the

December 2022

22
number of IVD embryos (~15.1%). Yet, the total number reported in goats increased 13.6% in 2021.

For the first time, over one million IVP cattle embryos were transferred worldwide, a 32.8% increase compared with 2020 (1,166,034 vs. 878,181, respectively). Together, IVP and IVD embryos accounted for almost 1.5 million transfers in 2021. The increase in the number of IVP embryos was particularly noticeable in North America (+34.5%) and South America (+37.0%), reflecting the intense activity in countries such as the United States, Mexico, Brazil, and Colombia. In fact, North and South America accounted for 88.1% of all bovine embryos transferred in 2021.

The proportion of frozen-thawed IVP embryos transferred last year was slightly greater than in 2020 (41.3% vs. 39.5%, respectively). Although proportionally more frozen-thawed IVD embryos have been transferred compared with their IVP counterparts (60.5% vs. 41.3%, respectively), cryopreserved IVP embryos accounted for 32.6% of all transfers in 2021, a greater proportion compared with the 12.8% observed for cryopreserved IVD embryos.

In summary, the already heated market for embryo technologies observed in 2020 was boosted in 2021, resulting in the reach of new milestones of embryos produced and transferred. Although this was a general trend for different species and regions, the increase in embryo activity was particularly evident in cattle and within the Americas.

2. Introduction

The IETS Data Retrieval Committee is the committee in charge of gathering, organizing, and publishing the statistics of the embryo industry in domestic farm animals. This year, we present our 31st annual report showing data on global activities related to in vivo and in vitro embryo collection and transfer in 2021. The results shown in the present report represents the main trends of the embryo industry worldwide in ruminants and horses.

3. Methodology

Data collection followed the standard methodology used in previous years, as defined by the Data Retrieval Committee and reported annually in the December issue of the Embryo Technology Newsletter. In summary, embryo technology activity in each country was either reported by a local data collector or reported individually by practitioners or commercial companies (e.g., in vitro embryo production

In several countries, the data collector is a member of the national embryo transfer/technology association: Argentina (Sociedad Argentina de Tecnologías Embriónarias, SATE), Brazil (Sociedade Brasileira de Tecnologia de Embriões, SBTE), Canada (Canadian Embryo Transfer Association, CETA), Mexico (Mexican Embryo Transfer Society, META), Peru (Asociación Peruana de Reproducción Animal, ASPRA), and the United States (American Embryo Transfer Association, AETA). For the member States of the European Union and other European countries, data has been submitted by a regional collector on behalf of the Association of Embryo Technology in Europe (AETE). Data has also been reported to IETS by ET teams or companies working abroad. In a few countries, this was the sole source of information on embryo activity. In the case of similar data reported by a local representative, however, data coming from such teams or companies were discarded, to avoid double-reporting. The list of data collectors and local collaborators is shown in Appendix 1.

Data were directly uploaded into the IETS website by the national collector or sent to the Chair of the Data Retrieval Committee. The software managing the database generate .csv files with data organized by criteria defined in the data submission form. A summary of the results is shown in Tables 4 to 14, by region, technology (in vivo-derived [IVD] or in vitro-produced [IVP]), and species. South American numbers include those collected from South and Central America countries. Data has also been used to build historical series and ranks, shown in Figures 2 to 5 and in Table 15. Detailed country information (Appendix 2–6), are available as supplemental files at the IETS website (www.iets.org/Committees/Data-Retrieval-Committee).

4. Results

Data Retrieval

Only minor changes occurred in the number of countries reporting ET data from the most representative farm species in 2021. In Europe, the only change was that we were able to recover data from Poland (IVD and IVP cattle embryos), but not from Hungary. In Oceania, we did not recover data from New Zealand. In South America, we obtained data from Chile and Costa Rica (IVP cattle embryos) which were absent in 2020. The number of countries reporting cattle IVD embryos remained the same as in 2020 (31), whereas those reporting IVP embryos increased from 26 to 29. In sheep, changes were that Greece, but neither Portugal or Sweden, reported ET activity. In goats, we did not receive data from Brazil. In horses, we now have data from four more countries: Colombia, Portugal, Poland, and Estonia. Once again, in 2021 we were not able to recover any data from Asia. Nonetheless, the Japanese Embryo Transfer Society is working to resume data retrieval and it is likely to report data next year.

Although data collection remains a challenge in Asia and Africa, the overall low variation in the number of countries reporting data has made it easier to track changes in numbers throughout years and, thus, build historical series and provide interpretation of the main trends of the embryo industry worldwide.

As in 2020, data of embryo exports reported by the AETA and by CETA practitioners working abroad provided indirect evidence of ET activity in 16 countries that did not report any data, including six in Asia. In many cases, the low number of embryos imported (a few dozen) suggests an incipient embryo activity. Still, China imported 9,342 bovine embryos from the United States, which is not only a significant amount, but in fact a number of embryos greater than that reported by two-thirds of the countries submitting data to the IETS. Together, countries with direct or indirect ET data account for 48.3% of the world cattle population.

Embryo Industry in Numbers

Cattle, IVD. The number of flushes, ova, and transferrable embryos collected in 2021 by region is shown in Table 4 and the number of transfers is shown in Table 5. A total of 386,374 transferrable IVD embryos were collected, which is 6.8% greater than 2020 (361,728). This is the first increase in the number of IVD embryos since 2015. This increase is likely, however, to reflects the current positive scenario of the embryo industry rather than a change in the trend toward the adoption of in vitro technologies. In fact, the increase in the number of IVP embryos reported within the same period was far more significant (31.5%). Among regions, the number of collected IVD embryos in 2021 increased in Europe (+6.2%), North America (+9.7%) and Oceania (+218.5%), but decreased in South America (~27.7%) compared with

December 2022
In spite of the increase in absolute numbers, cattle IVD embryos now represent only 20.3% of the total of embryos recorded and 21.2% of the embryos transferred worldwide, in both cases a slight reduction compared with 2020 (it was 23.8% and 25.1%, respectively).

The main features related to the collection and transfer of IVD embryos remained quite unchanged. Europe and North America still account for the majority of IVD embryos collected and transferred (90.6% and 90.3% of the total, respectively, in 2021). We detected a slight decrease in overall superovulation efficiency, with an estimated average of 9.4 ova and 5.8 transferable embryos per flush worldwide. Europe was the only region where IVD embryos were collected predominantly from dairy cows and heifers (80.9%), feature observed in 19 out of the 23 countries reporting data within this region (82.6%). In the Americas, IVD embryos were collected more frequently from dairy breeds only in Canada (56.0%) and Colombia (68.7%). Sex-sorted semen was used in 31.7% of flushes in dairy breeds, but in only 4.9% of the flushes in beef breeds.

The proportions of frozen-thawed or fresh IVD embryos transferred in 2021 were similar to those observed in 2020 (59.5% vs. 40.5%, respectively). The transfer of cryopreserved embryos was greater in beef than in dairy breeds (66.9% vs. 53.4%). The proportion of transferred frozen-thawed embryos was slightly greater in North America than in South America or Europe (62.1% vs. 53.9% and 58.5%, respectively).

Cattle, IVP. The production of embryos in vitro in 2021 is shown in Table 6 (OPU-collected oocytes) and Table 7 (abattoir-derived oocytes). We observed a remarkable increase in the number of IVP embryos reported in 2021 (1,521,018 vs. 1,156,422 in 2020; +31.5%), which led to the increase of 25.6% in the world’s total, the greatest since 2003. The number of IVP embryos recorded in 2021 increased in all regions but Europe (−10.7%), compared with 2020. As observed in 2020, European numbers were affected by the retraction in the ET activity in Russia, which accounted for 34.5% of the IVP embryos from that continent in 2020, but almost ceased the activity in 2021 (−99.9%). Conversely, in the Netherlands and Germany, the second and third largest countries in regard to IVP embryo numbers in Europe, recorded substantial increases in 2021 (+22.9% and +9.1%, respectively).

The trends observed for IVP embryos in 2021 were mostly driven by the scenario in the Americas. North America and South America accounted for 95.7% of the IVP embryos, and in both regions, numbers increased in a similar fashion (+32.1% and +35.3%, respectively, compared with 2020).
2020). A noticeable increase in IVP totals occurred in Mexico (+244.6%) and in Colombia (+187.3%). However, the increase observed in the United States (+22.0%) and in Brazil (+20.6%), the first and second largest countries in IVP numbers, resulted in an additional 115,768 and 75,534 embryos in the world’s totals, respectively. It is noteworthy that numbers from Brazil are likely to be significantly underestimated, due to the evident difference between the number of embryos reported to the breeders’ associations and the number of ET sheaths sold in the country (1,189,593 in 2021). This difference increased from 8.1% in 2015 to 171.6% in 2021, perhaps effect of the growing market of unregistered, low-cost embryos in Brazil.

A contrasting situation occurs regarding the use of FSH stimulation before ovum pick-up (OPU). In all European countries and in Canada, the vast majority of the IVP embryos recorded have been produced after FSH stimulation (99.3% and 100.0%, respectively), whereas in other North

</table>
American countries as well as Oceania and South America, FSH is rarely used (2.4% of the OPUs).

The number of IVP embryos generated using abattoir-derived oocytes in 2020 increased in Europe (+56.2%) and North America (+97.1%), but decreased in South America (−29.0%), resulting in an overall decrease of 7.5% (21,882 vs. 23,649 in 2020). The proportion of IVP embryos generated from abattoir oocytes remains very low (1.4% of total).

The number of transfers of IVP embryos in 2021 is shown in Table 8. Both the absolute number and the proportion of IVP embryos actually transferred in 2021 increased compared with 2020 (1,166,034 [76.7%] vs. 878,181 [75.9%], respectively). As expected, the number of IVP embryo transfers decreased in Europe (−37.8% relative to 2020), and increased elsewhere (+30.5% in Africa, +34.5% in North America, +23.1% in Oceania, and +37.0% in South America). Although the United States recorded more IVP embryo production than Brazil (642,559 vs. 441,787, respectively), the proportion of embryos actually transferred was lesser in the former compared with the latter (56.5% vs. 98.5%). Thus, Brazil remains as the leader in transfers of IVP embryos worldwide (435,359, corresponding to 36.6% of the world total).

The proportion of frozen-thawed IVP embryos transferred in 2021 was slightly greater than in 2020 (41.3% vs. 39.5%, respectively), but has increased consistently over the last years (it was <10% in 2012). This, combined with the current trend toward a rapid expansion in the use of in vitro technologies, accounted for the growing share of cryopreserved IVP embryos in the total of transfers, which reached 32.6% in 2021.

Table 9 shows data regarding embryos micromanipulated for sexing or genotyping in 2021. These numbers are likely underestimated, but are useful to illustrate the general trends for these technologies. Consistently with what has been observed in previous years, both sexing and genotyping decreased in IVD, whereas increased in IVP embryos (−39.3% and −22.1% vs. +11.4% and +14.9%, respectively).

**Other species.** The numbers of IVD and IVP embryos reported in 2021 in species other than cattle are shown in Tables 10 (sheep), 11 (goats), 12 (horses) and 13 (cervids and buffaloes). Embryo activity in sheep followed the trends observed in cattle, with an increase in both numbers of IVD and IVP embryos recorded and transferred in 2021 (+38.1% and +104.4% for IVD, and +379.6% for IVP, respectively, compared with 2020). Australia leads the collection and transfer of IVD sheep embryos (53.1% and 30.5% of world totals, respectively), whereas the USA accounted for most of IVP sheep embryos (77.2% and 94.4%, respectively). A contrasting scenario has been observed for goat embryos. The total number of embryos recorded increased 13.6% from 2020 to 2021. However, the number of IVD embryos collected and transferred decreased (−15.1% and −17.9%, respectively), whereas the numbers of IVP embryos increased substantially (+179.3% and +305.6%, respectively). As observed in 2020, the United States accounted for most of the IVD and IVP goat embryos (77.2% and 94.4%, respectively) reported in 2021 worldwide.
In horses, the increase in the number of embryos recorded in 2021 (+9.6%) was mainly driven by the increase in IVP (+34.5%), as the number of IVD embryos remained similar to 2020 (25,475 vs. 25,219, respectively, +1.0%). Once again, Brazil leads the collection of IVD horse embryos (23,420; 91.9% of world total), whereas Italy was the country with more IVP embryos (6,764; 58.2% of world total). Italy, however, exported 51.7% of the IVP embryos and only 7 fresh and 727 frozen-thawed embryos were transferred within the country.

In 2021, the number of cervid embryos reported decreased substantially (−89.1%), partially due to the lack of data from New Zealand, but also due to the reduction in numbers from the USA (−91.4%). On the other hand, the number of IVP embryos reported increased (from 15 to 226, +1,406.7%), thanks to Mexico and the United States. Embryo transfer activity in buffalo was reported only by the United States, and only for IVP embryos.

Exports. The numbers of embryo exports are shown in Table 14. In cattle, the number of IVD embryos exported in 2021 decreased in dairy (−10.1%) but increased in beef breeds (+40.5%), resulting in an overall increase of 2.0% relative to 2020 (30,808 vs. 30,211). The number of IVP cattle embryos exported in 2021 decreased (−6.2%). Nevertheless, the number of countries reporting exports of IVP embryos increased from 4 in 2020 to 7 in 2021. All exported cattle IVP embryos were produced with oocytes recovered by OPU.

Three countries reported exports of IVD sheep embryos, which increased by 379.6% (1,199 vs. 250 in 2020). Moreover, 200 goat IVD embryos were exported by Spain. Italy accounted for all horse IVP embryos exported, which increased 30.2% compared with 2020.

### Historical Series and Trends

The historical series of cattle embryo production (IVD, IVP, and total) in the past 20 years (2002 to 2021) is shown in Figure 2. The current trend of growth in world total has been already detected in 2020. In 2021, however, we observed a steep rise (31.5%) in the number of IVP embryos compared with 2020, the greater rise since 2017. Actually, in absolute numbers this was the greatest change from the immediate previous year (+363,596 embryos) in our historical series. Due to the small change in the number of IVD em-

</table>
bryos (+6.8%), the rise in IVP numbers reflected directly on the total numbers. The current growth rate of IVP embryos is similar to the one observed in the early 2000s, (average +35.8% per year from 2002 to 2006), which was followed by a period of slower increase in numbers (+4.6%) between 2007 to 2015. On the other hand, in spite of the increase observed in 2021, the number of IVD embryos has declined consistently over the past years (on average −4.0% per year), after reaching its peak in 2005 (789,972).

The numbers of IVP and IVD embryos recorded per region are shown in Figures 3A and 3B, respectively. The trend favoring IVP embryos in North and South America, regions accounting for most of the embryos produced worldwide, has been similar (+32.1% and +35.3%, respectively)

**Figure 2.** Number of bovine embryos (in vivo-derived [IVD], in vitro-produced [IVP], and total) recorded in the period 2002-2021.

**Figure 3.** Number of embryos produced or collected in cattle in the period of 2002-2021, by continent. (A) In vitro-produced [IVP] embryos; (B) In vivo-derived [IVD] embryos.
and are in contrast with Europe, where numbers declined (−10.7%). Conversely, the rebound in the number of IVD embryos was observed in North (+9.7%), but not in South America (−27.7%), region in which the vast majority of embryos recorded is currently produced in vitro (96.8%).

The number and the percent share of frozen-thawed IVD and IVP embryos transferred from 2002 to 2021 are shown in Figures 4A and 4B. As expected, the proportion of IVP embryos transferred in 2021 increased from 74.9% to 78.8% of the total (IVP+IVD). However, this increase was associated with a rise in use of cryopreserved embryos, rather than of fresh embryos, when compared with 2020 (from 29.6% to 32.6% vs. 45.3% to 46.2% of all embryos transferred, respectively). The share of IVD embryos transferred as frozen-thawed or fresh decreased in the same proportion (from 10.2% to 8.4% and from 14.9% to 12.8%, respectively).

**Embryo Industry Rank**

The absolute numbers of embryos produced and transferred provide a dimension of the embryo industry within each country. These numbers, however, are only an indirect indicator of the average adoption of the technology by farmers. Therefore, we here propose an index based on the number of embryos produced per 10,000 heads of cattle, aiming to evaluate the intensity of embryo technologies use by each country.

Based on this criterium, the United States is not only the country with the greatest bovine embryo production, but also ranks first in intensity of ET use, with an index of 85.5. In contrast, Brazil ranks second in embryo production, but this country has the largest commercial cattle inventory in the world; thus, Brazil ranks only 16th in the intensity index. The difference between total embryo production and the intensity of technology use is depicted as density maps in Figure 5 (A and B).

**5. Discussion**

The increase in the number of embryos collected and transferred worldwide in farm species observed since 2020 has been consistent with the long-term trends of the embryo industry. Nevertheless, it contrasts with the expected effects of the economic and social crisis subsequent to the outbreak of Covid-19 and the declaration of a global pandemic status by the World Health Organization (WHO) on March 11, 2019. In fact, to some extent the pandemic actually had a negative impact on the embryo industry, particularly by disturbing logistics and supply chains of consumables, media, and plasticware. This negative impact, however, was counterbalanced by a growing international demand for food and by the rise in prices of animal protein, which directly boosted the pursuit for superior genetics and, ultimately, for the use of embryo technologies, as discussed previously.

In this regard, we thus speculate that this conjuncture has made 2021 even more favorable for the embryo industry, explaining the steep rise in ET numbers, particularly in cattle and sheep. Although the peak of deaths during the pandemic occurred in 2021, the development of vaccines and rapid immunization of a large percentage of the population created the economic conditions for a rebound in global GDP.
(from −3.3% in 2020 to +5.8% in 2021). On the other hand, international meat prices remained high, reflecting on the demand for ET services and embryo market perspectives. Clear evidence to support the positive scenario of the embryo industry observed in 2021 is the remarkable raise in the number of IVP embryos recorded and transferred, which for the first time reached 1.5 million and 1.1 million units, respectively.

All countries ranking on the top 10 in embryo production in 2020 recorded increase in 2021 numbers. Moreover, in addition to Argentina, Brazil, Canada, and the United States, two more countries reported over 50,000 embryos: Colombia and Mexico. The heated demand for ET is also likely to explain the shift in the previous trend toward a decrease in the records of IVD embryos observed since 2015. Instead, an increase in use of IVD embryos was observed in North America and Europe. Not in South America though. Still, the contribution of IVD embryos to the totals in the latter was already very low (<10%) even before the pandemic, and the favorable scenario for ET in 2021 seemed not enough to change this.

Despite the milestones reached, one shall consider that the current numbers may still be most likely underestimated. Since 2017, we do not receive ET data from Japan, which used to be the country with the most active embryo industry in Asia. Moreover, embryo export data provide evidence of ongoing ET activity in other countries within that continent, none of them reporting data to the IETS. In some particular cases (e.g., China), the numbers of embryos imported are not neglectable, and it is not unlikely that local embryo production is going on too. Another trend to watch is the emergence of new markets that may skip the current data retrieval procedures and, thus, lead to underreporting. This seems to be the case in Brazil, where large-scale in vitro embryo production programs have been used to generate replacement heifers for small farmers or zebu × taurus crossbreds for feedlots and the meat market, which are usually not reported to the breeder’s associations. In fact, the difference between the number of ET sheaths sales and embryos actually reported has been progressively increasing since 2015 and suggests that less than half of the embryos actually produced may have been reported in 2021. Altogether, these underreporting...

ing scenarios may have hidden the real importance of the embryo industry for livestock production worldwide. Still, data available provides a good picture of the main trends and potentials of the ET technology, which may be not fully understood yet. The current rise in IVP numbers show how suitable the technology is to timely respond to market demands, either by intensifying animal breeding programs or exploring new market niches.

Lastly, we propose a newly created index to evaluate not only the raw numbers but also the intensity of ET technologies use among distinct countries. After ranking by this index, we were able to have a better view of the importance of embryo technologies in countries with relatively small absolute numbers, such as Panama or Finland. Additionally, we can forecast a potential for expansion of the embryo market in countries like Argentina, Australia, and Brazil, which have large cattle inventories (almost 300 million heads of cattle together; 18.7% of the world total) and an already established and active embryo industry, but still rank low on the intensity index list (18th, 19th, and 16th, respectively). Similarly, we could use this index in other farm species to speculate about the potential impact and future development.

**Figure 5.** World density map depicting (A) total bovine embryo production, and (B) number of embryos per 10,000 cattle heads in each country in 2021. Image generated using Microsoft Excel.
of embryo technologies, considering herd size and the importance of the livestock sector for the economy in a given country.

6. Acknowledgments

The Data Retrieval Committee thank the efforts of all regional data collectors, as well as all practitioners or representatives of ET companies who reported data to the database or directly to the Chair. The comprehensiveness of the present report is the result of the volunteer collaboration of all these colleagues. The Chair also thank Luiz G. Siqueira for reviewing this report.
